

C1 What is interaction design

107062501 江秉翰

Abstract :

A central concern of interaction design is to develop interactive products that are usable. A well-designed product will make users feel easy to use and willing to use. On the contrary, a poorly-designed product may confuse users and keep them from using it.

Interaction design is about creating user experience that enhance and augment the way people work, communicate and interact. Interaction design is mostly carried out by multidisciplinary teams. This enables the teams to have different viewpoints on several objectives and be more creative. However, it may also lead team members hard to communicate to each other.

The user experience is central to Interaction Design. It includes users' overall impression of how good it is to use.

More recently, *user experience goals* have been concerned with explicating the nature of the user experience. As same as *usability goals*, both of them are typically operationalized as questions.

Design principles are used by interaction designers to aid their thinking when designing for the user experience. 5 design principles have been promoted in the book, including *visibility*, *feedback*, *constraints*, *consistency*, and *affordance*. However, when applying more than one design principles in interaction design, trade-offs can arise between them. As a result, it's challenging for designer to decide a best interaction design utilizing multiple design principles.

Feedback :

Actually I'm not sure whether we have to write 2 abstracts and feedbacks to the 2 articles. Because this article is written in English, I choose to write the abstract and feedback in English, too. Hope it won't bother.

I come to read this chapter after finishing another article (W1 – 設計不良的日常用品). I think the concept of this two articles are similar – introducing Interaction Design, while “What is interaction design” addresses more details and gives lots more examples.
