

Visioning a New Way to Work

Assistive Devices for those on the Spectrum

The visioning process was an integral part in the designing of our proposed device, especially after the affinity diagram was accomplished. For the visioning process in our case we had considered visions from two fresh perspectives.

Vision 1: Sam Churchill, 70, War Veteran who actively suffers from Vertigo as well as PTSD (Post Traumatic Stress Disorder) who occasionally suffers from brief episodes of attacks, would like to go downtown in order to catch a coffee with his pals. He insists on being independent and not relying on his family, while on his way to the coffee house. Sam begins to sense that he is about to have an episode of PTSD, however since he is using our Device. Sam managed to just in time activate the SOS feature, immediately alerting his family about his location as well as the Emergency personnel.

- **Advantage:** Provided immediate live updates of his location to his family so that they were able to locate instantly
- **Disadvantage:** It was unable to provide the people in the vicinity any information on how to handle the situation appropriately

Vision 2: Gloria Burges, 5, is a young girl who loves painting and cuddling with her service dog. Gloria was diagnosed with Downs Syndrome very early on in her life. Her parents however wished that she would have as normal of a life as possible as any other kid. On one weekend, while Gloria's mum had been watching over her she had to briefly take a break. Unfortunately, Gloria could sense the onset of an episode and swiftly utilizes the "Calming" feature of the assistive device to play soothing music while promptly alerting her parents about her oncoming episode and her mother could appropriately respond before the situation got out of hand.

- **Advantage:** There are preloaded features that can either delay or prevent an oncoming episode
- **Disadvantage:** It was unable to analyze the patient's emotion in order to predict an oncoming episode.
